## Overview

- Case Study: Automated software distribution for airplanes
- Dynamic, ad-hoc trust relationships
- Using SecPAL to specify authorization and trust policies
- Conclusion

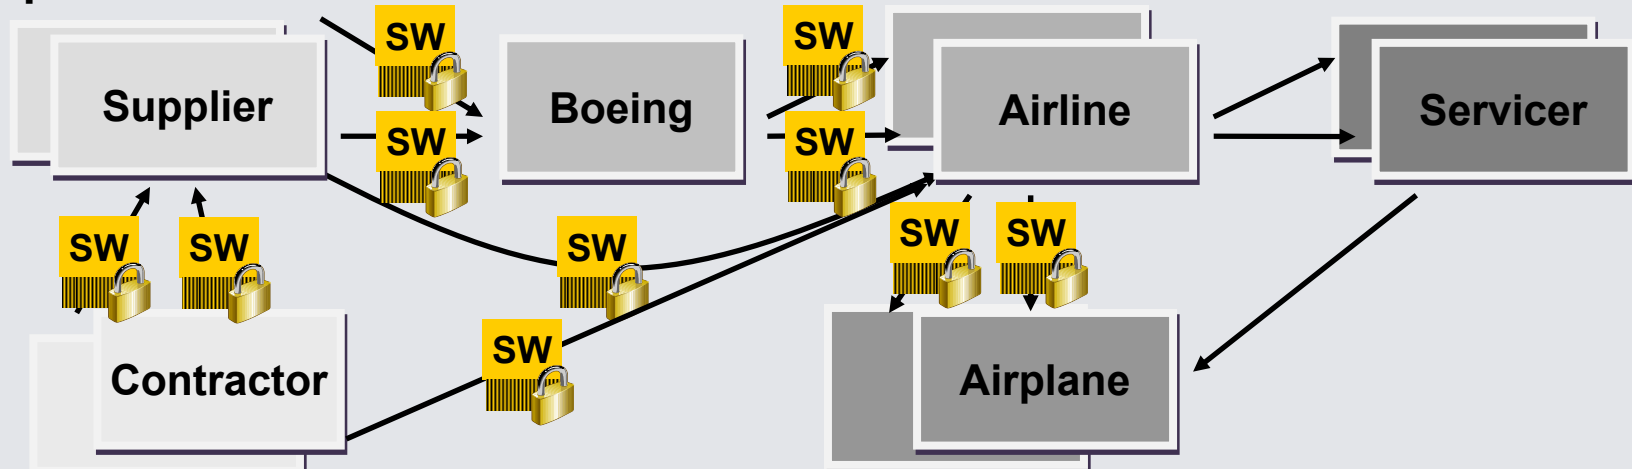

## Case Study: Software distribution chain

- Electronic (i.e. network-based) distribution of software for airplanes.
- Software is produced by suppliers of the manufacturer (Boeing) or their contractors
- Airlines receives software parts from Boeing, suppliers or contractors, and send them into airplanes.
- Airlines commissions local service providers to perform the installation.

## Case Study: Security aspects

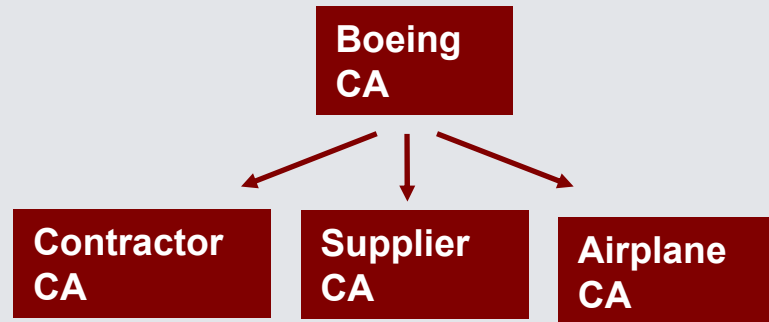

- SW parts in the airplane might perform safety-critical tasks, hence the SW distribution has to be secure.
- Security requirement: Only unmodified SW parts that have been released by trusted producers are installed in airplanes.
- Hence every party along the distribution chain should **authenticate the senders and check if they are authorized** e.g. to release parts.
- Authentication and integrity can be ensured by **signatures** on SW. **PKI certificates** have to be verified – PKI certificate chains have to be in place.

# PKI based stable trust relationships

There are several options for building PKI certificate chains.

## 1. Hierarchical CAs

## 2. Bilateral cross-certification

## 3. Bridge CA

## Decentralized, dynamic characteristics do not fit with PKI

- PKI establishes stable, long-term trust relationships and requires central management:
  - Certificates have a lifetime of one to several years.
  - All options require high organizational effort and costs: Certificate policies have to be agreed and enforced. Certificate Revocation Lists (CRLs) have to be managed.
- The case study is decentralized. The involved parties are **globally distributed, highly diverse** and their relationships (contractors, service providers) are **dynamic**. Hence building PKI between all parties is not feasible.
- Ad-hoc: holding partner certificates in local certificate stores. Implicit and very hard to manage!

## Overview

- Case Study: Automated software distribution for airplanes
- **Dynamic, ad-hoc trust relationships**
- Using SecPAL to specify authorization and trust policies
- Conclusion

# Dynamic, ad-hoc trust relationships in the case study

## Stable relationships

**Boeing – Airline:** Airlines can verify Boeing’s certificates.

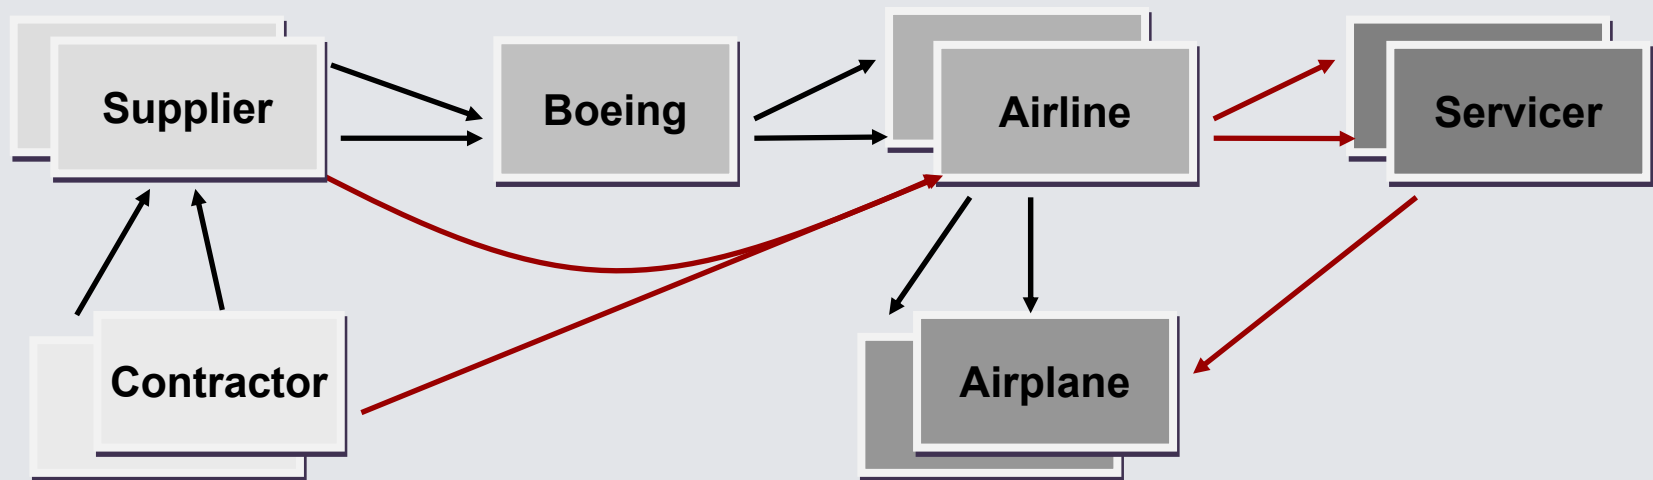

**Airline – Airplane:** The airplane can verify credentials of its airline

## Dynamic relationships

**Airline – Suppliers:** Airlines do not manage relationships with suppliers.

**Boeing – contractors:** Boeing is not directly involved with contractors.

**Airplane – Service providers:** service providers not known by the airplane

# Measures to handle dynamic, ad-hoc trust relationships

Stable, long-term trust	Dynamic, decentralized trust
<ul style="list-style-type: none"><li>- Authentication by long-term credential (certificate, password)</li><li>- Incorporated into IT infrastructure (user accounts,..)</li><li>- Contracts and agreements.</li></ul>	<ul style="list-style-type: none"><li>- <b>Delegated authentication by short-term security tokens</b>, with a short validity (no revocation required) issued within a stable relationship, and used between decentralized partners.</li><li>- <b>Explicit chains of trust</b>. Dynamic trust relationships are used to establish other dynamic relationships.</li><li>- <b>Attribute-based authorization</b>, using information like roles, context, etc.</li></ul>

## Policies to specify authorization and trust

- Conditions and constraints have to be specified **explicitly** in policies.
  - Which security tokens are accepted?
  - Under which conditions are chains of trusted formed?
  - Which attributes are required to obtain authorization for which actions?
- Policies have to be **unambiguous and easy to interpret**.
- Automated evaluation of policies.

## Overview

- Case Study: Automated software distribution for airplanes
- Dynamic, ad-hoc trust relationships
- Using SecPAL to specify authorization and trust policies
- Conclusion

# SecPAL can be used to specify policies for dynamic, decentralized authorization and trust.

- SecPAL is based on logic programming (Datalog):
  - Arbitrary attributes can be defined.
  - Automatic reasoning to deduce valid consequences.
- SecPAL offers constructs to specify delegation.
- Example:
  - **Airline** says **p** is accepted if **p** is type2-critical AND **p** is approved.
  - **Airline** says **Boeing** can say **x** is a supplier.
  - **x** can say **y** is a contractor till **t** if **x** is a supplier AND **currentTime** < **t**.
  - **y** can say **p** is approved if **y** is a contractor.      Delegation => chain of trust
  - **Boeing** says **Honeywell** is a supplier.
  - **Honeywell** says **EquipTech** is a contractor.
  - **EquipTech** says **Part456** is approved.      Security tokens with attributes

Request: **Part456** is accepted?

# SecPAL policy for authorization of suppliers and contractors

FlightMedia says	Honeywell says	EquipTech says
<i>Assertion tokens</i> Part789 is approved.	<i>Assertion tokens</i> Part123 is supplier-approved. EquipTech is a contractor till 2011.	<i>Assertion tokens</i> Part456 is approved. FlightMedia is a contractor till 2012.

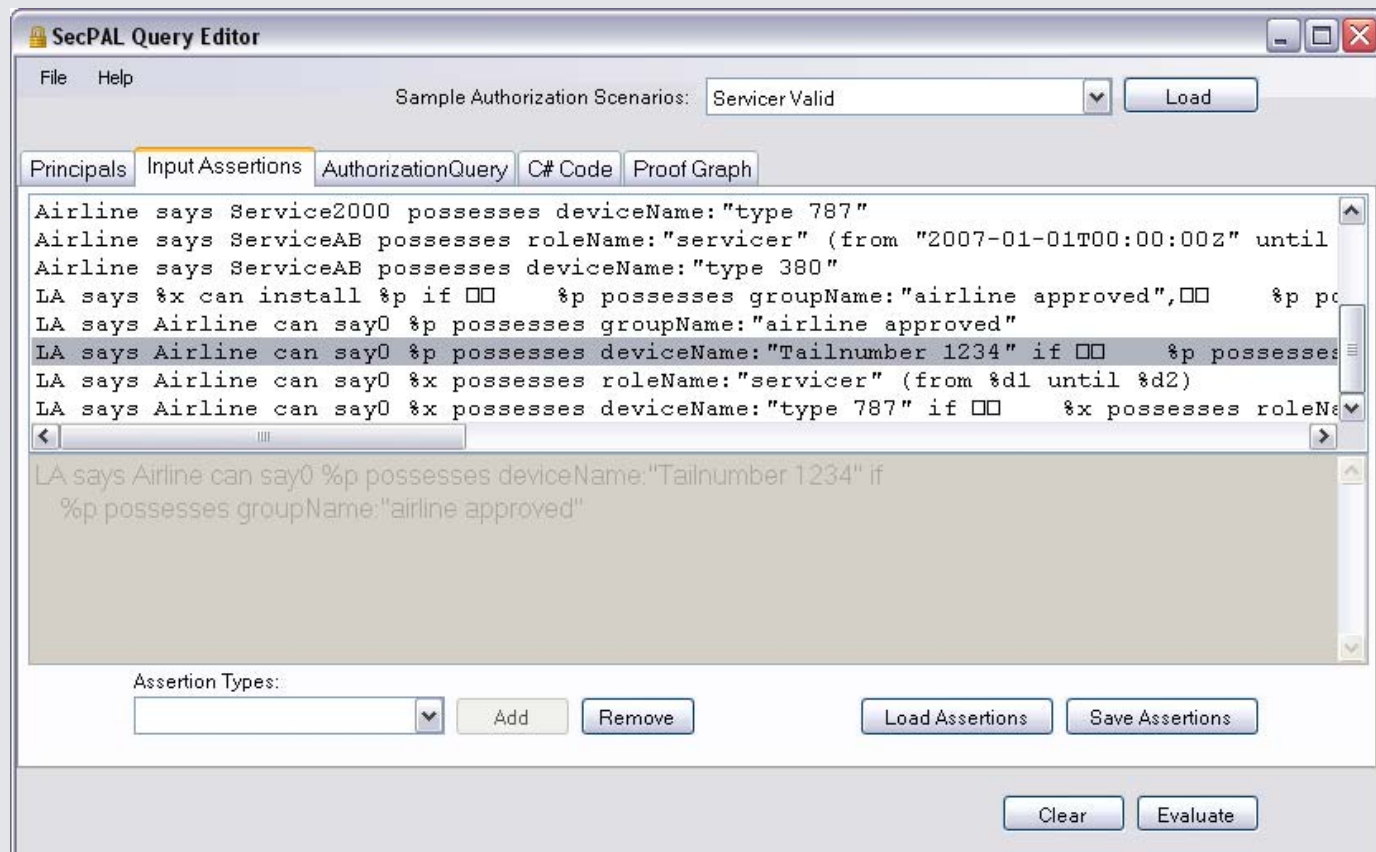

Boeing says
<i>Assertion tokens</i> Honeywell is a supplier.      Part123 is type1-critical.

Airline says
<i>Delegation rules</i> Boeing can say x is a supplier. x can say y is a contractor till t if x is a supplier AND currentTime < t. x can say y is a contractor till t1 if x is a contractor till t2 AND t1 < t2. y can say p is approved if y is a contractor.
<i>Authorization rules</i> p is accepted if p is type2-critical AND p is approved. p is accepted if p is type1-critical AND p is supplier-approved

# Demonstrator

Implementation of SecPAL query evaluation is available: C# class libraries and a GUI (SecPAL Query editor) to start evaluation and examine proof trees.

## Related work

- **The SAML protocol and SOAP message security (WS-\*) are established examples of token-based security models.**  
(Different goals than SecPAL, namely Single Sign-On, Identity Federation and SOAP message authentication and protection).
- **SAML assertions are a widely-used form of security tokens.**
  - **Attributes can be used in SAML assertions.**
  - **SAML can be combined with XACML (eXtensible authorization markup language) to specify centralized authorization. No delegation constructs.**
- **A range of logic-based authorization policy languages have been proposed for differing purposes.**

## Conclusion

- Our case study demonstrates the demand for a decentralized authorization policy language for **IT system with networked devices in the field performing critical tasks.**  
(Other examples: automobiles and public transport, energy distribution, programmed machine tools, medical devices ...)
  - PKI infrastructure including all parties is not feasible.
  - Inserting certificates into local certificate stores is hard to manage
- SecPAL is suitable to express decentralized authorization and trust policies as required by our case study.
- The resulting policies are easy to grasp for non-experts.
- Standardization and binding to existing transport protocols would be required to promote usage.

Thank you for your attention.
